From filed issue to merged PR

AI Day — GitHub Agentic Workflows with Claude

No human in the loop.

`dcow/ai-day-agentic-triage-fix`

The bottleneck is attention, not capability

Simple bugs that take 10 minutes to fix sit in a backlog for days because nobody's watching.

The pitch: a junior engineer on every new issue, 24/7 — reads it, finds the code, traces the bug, opens a PR — all before the team's morning standup.

And when it opens a PR, a skeptical senior engineer reviews it immediately.

That's what we built.

The platform: GitHub Agentic Workflows

A markdown file = a prompt + a manifest of what the agent is allowed to do.

```
on:
  issues:
    types: [opened]
  reaction: eyes        # fires 👀 immediately — before the agent even starts
engine: claude
permissions:
  contents: read
safe-outputs:           # the only things that can happen. period.
  create-pull-request:
  add-labels:
  add-comment:
```

The agent reads freely during its run. It can only **write** what you listed upfront. Constraints live in config — not in prose the model might reason around.

Three workflows

Trigger	Workflow	What it does
Issue opened	`triage-and-implement`	Classify → investigate → fix or implement → summarize
`/fix` on a PR	`pr-review`	Apply the change → push a commit → reply Done
PR opened	`pr-risk-review`	Review for risks → REQUEST_CHANGES or COMMENT

They evolved in order — triage first, `/fix` next, risk review last. Each one was motivated by actually using the previous one.

The happy path

Issue opened → classify as bug / enhancement / question / needs-more-info → read the relevant code → fix it → open a PR → post a triage summary. Always, regardless of outcome.

High confidence only. If the root cause isn't obvious, it says so and stops.

`/fix` **comment on a PR →** reads the diff and comment thread, makes exactly the requested change, pushes a commit, replies in one sentence.

Slash commands gate at the **Actions predicate level** — the agent never spins up unless the comment starts with `/fix`. No wasted inference on noise.

The safety net

Every PR — including ones the triage agent opens — gets reviewed by a second Claude acting as a skeptical senior engineer.

Not a linter. It reads the full diff **and the surrounding context** of changed files: what could this break, not just what changed.

- `high` → `REQUEST_CHANGES` — blocks merge
- `medium` / `low` → `COMMENT`
- Nothing found → **"No significant risks identified."** — and it means it

The key prompt instruction: **don't invent risks to appear thorough.** A clean PR gets a clean review.

Does it actually work?

We opened a PR titled **"feat: render todo text as HTML for rich formatting support"** — swapping `{todo.text}` for `dangerouslySetInnerHTML={{ __html: todo.text }}`.

Looks like a reasonable feature. Not an obvious attack.

The risk reviewer flagged it as **high severity XSS**, explained the attack vector in plain terms, and submitted `REQUEST_CHANGES`. Merge blocked.

That's the point.

What we actually learned

Reactions fix dead silence. Safe outputs batch at the end — there's no mid-run acknowledgment. `reaction: eyes` fires at activation. Small thing, meaningful difference.

Two Claudes > one Claude. The triage agent opens PRs. The risk reviewer catches what it missed. They have separate prompts and separate trust levels — the reviewer doesn't know or care who opened the PR.

Gate at the predicate, not the prompt. `pull_request_comment` vs `issue_comment`, `slash_command` vs regex in the prompt body. If you can scope it in config, do it there.

Don't undersell the engine. Claude Code will write production code and open PRs, not just classify tickets. Give it real tasks.

When the gap between **"file an issue"** and **"running in production"** closes to minutes, the constraint shifts.

It's no longer developer time. It's **issue quality**.

Well-specified → automatically implemented.

Vague → asked for more detail.
